

MEAN ANNUAL INCREMENT IN THE FORESTS OF GARHWAL HIMALAYAS RELATED WITH SOIL AND GROUND LITTER PROPERTIES

R.M. SINGHAL AND S. SONI

*Social Forestry Division,
Forest Research Institute, Dehra Dun (India)*

Introduction

Site factors are important determinants of forest productivity within a climatic region and physiographic stratum with soil being the major site component. Ralston (1964) and Carmean (1975) while reviewing research in North America on soil factors vis-a-vis site productivity concluded that the factors responsible for controlling the productivity of forests were the moisture, nutrients and aeration, and when other site factors kept uniform then soil nutrient level is more important (Moller, 1974; Pritchett and Gooding, 1975; Waring, 1973). The character of the forest floor, influencing many soil properties was also reported to be connected with the growth and development of forest stands since controls properties of organic matter which in turn regulate the regeneration of trees (Mathur and Bhatnagar, 1964). George (1977) and Negi (1984) studied the forest productivity vis-a-vis soil nutrients in the tropical and man-made forests but no such work is reported for the forests of the temperate regions particularly Garhwal Himalayas which are otherwise very important from management point of view. The present study which deals with the mean annual increment in these forests of deodar, chir and oak forests

as related with soil properties and litter composition is an endeavour in this direction.

Site

The area under investigation lies in the Dhanaulti Block of Mussoorie Forest Division (U.P.) at an elevation ranging about 2000 m to 2750 m above m.s.l. The average rainfall of the area is 254 cm with maximum 75.21 cm (August) and minimum 0.41 cm (November). The mean maximum and minimum temperature for the hottest month are 30°C and 16°C and for the coldest month 9.4°C and 3.8°C respectively. The other site features, already described earlier by Singhal and Soni (1989) have been presented in brief in Table 1.

Experimental

Eight sites, representing the deodar (*Cedrus deodara*), chir (*Pinus roxburghii*) and oak (*Quercus leucotrichophora*) vegetational types were selected for the study. In each study site woody species were enumerated by the methods of Khan and Gupta (1960) and soil samples collected from the representative profiles. The collection of samples were done before the onset of monsoon. The soil samples so collected were analysed as per the methods of Piper (1950) and Jackson (1967) for different characteristics. The

Table I
General description of the sites

| Forest Type | Locality | Altitude (m) | Slope | | Soil depth | Predominant lithology |
|---------------------------------|---------------|--------------|--------|------------|------------|--------------------------------|
| | | | Shape | Degree (%) | | |
| <i>Cedrus deodara</i> | Dhanaulti 3 A | 2310 | Convex | 45 | Deep | Phylites, Shales and Sandstone |
| <i>C. deodara</i> | Dhanaulti 1 A | 2375 | Convex | 30 | Deep | Phylites, Shales and Sandstone |
| <i>C. deodara</i> | Dhanaulti 2 A | 2325 | Convex | 45 | Deep | Phylites, Shales and Sandstone |
| <i>C. deodara</i> | Dhanaulti 6 A | 2300 | Convex | 25 | Deep | Phylites, Shales and Sandstone |
| <i>Quercus leucotrichophora</i> | Dhanaulti 5 A | 2000 | Convex | 40 | Deep | Quartzites and Slates |
| <i>Pinus roxburghii</i> | Sorh 9 A | 2225 | Convex | 30 | Very Deep | Quartzites and Slates |
| <i>Q. leucotrichophora</i> | Than 3 | 2350 | Convex | 30 | Deep | Quartzites and Slates |
| <i>Q. floribunda</i> | Dhanaulti 1 B | 2350 | Convex | 50 | Very Deep | Quartzites and Slates |

Mean Annual Increment (M.A.I) of various species was calculated using field and volume tables available for this purpose.

Results and Discussion

It can be seen from Table 2 that the density of these forests varies between 1.9 to 6.4 trees 100 m², total basal cover varies between 160.87 to 9257.52 cm⁻² 100² and mean basal cover between 280.31 to 3627.94 cm² tree⁻¹ (Singhal and Soni, 1989).

As can be seen from Table 3, that the nutrient status in the litter varies from species

to species depending upon their total dry weight contents and other characteristics. The litter under deodar is richer in Ca, Mg, N, P and K contents in comparison to chir and oak may be due to their older age as also reported by Kaul *et al.* (1979) for the sal forests of Dehra Dun area.

The values of productivity, expressed in terms of mean annual timber increment has also been found to depend largely on the status of total organic matter in soil and on those factors which influence the input of organic matter and rate of its decomposition

Table 2
Quantitative characters of tree species

| Name of species | Frequency | Density Tree/100m ² | Abundance 100 ⁻² m | Mean basal cover cm ² Tree ⁻¹ | Total basal cover cm ² /100m ² |

in soils. It is seen that the productivity of particular stand is related with its soil organic matter content. It increases with an increase in the content of soil organic matter as appeared in its correlation with the deodar stands showing better productivity ($r=0.59$) as compared to chir ($r=0.57$) and oak ($r=0.56$). Productivity levels of these forest stands seem to be related with the relative degree of podzolisation of their soils as reported earlier by Singh and Singhal (1976) for similar soils.

It was interesting to see that the contents of micro-nutrients in the soil differ according to the type of vegetation under which these soils have developed and the mode of their accumulation. Their status is also dependent on the status of soil organic matter and the

productivity of the forests. The soils under deodar have higher content of Mn, Zn, Cu, Fe as compared to chir and oak. Higher contents of these micro-nutrients in the illuviated horizons as compared to other horizons shows migration of micro-nutrients with the clay and humus. However, when the status of these micro-nutrients is examined, keeping in view the mean increment levels of the individual forest stands it is seen that the micro-nutrients such as Mn, Co and Cu have a greater relationship with the productivity than the other elements under study. In deodar stands where values of M.A.I. are higher as compared to chir and oak the contents of all the micro-nutrients are also high whereas other stands have relatively less values. This is quite in agreement with the findings of Kaul *et al.* (1979).

SUMMARY

Elemental composition of the litter under deodar, chir and oak forests of Mussoorie Himalayas were characterised with soil properties and mean annual increments of the species. The study revealed that the forests under deodar had higher M.A.I. associated with higher content of Mn, Zn, Mg, Cu and Fe in their soils in comparison to the forests under chir and oak.

गढ़वाल हिमालयी भाग के वनों की माध्य वार्षिक संवृद्धि का वहाँ की मृदा और भूमि पर पड़े पर्णास्तरण से सम्बन्ध
आर०एम० सिंघल व एस० सोनी

सारांश

मसूरी के हिमालयी भाग में हो रहे देवदार, बाँज और चीड़ के वनों की मूल तत्व रचना की विशिष्टताओं का संबन्ध वहाँ की मृदा विशेषताओं तथा उन वृक्ष जातियों की माध्य वार्षिक संवृद्धि के साथ जोड़ा गया है। अध्ययन से पता चला है कि देवदार वनों की माध्य वार्षिक संवृद्धि अधिक है जो चीड़ और बाँज के मुकाबले में उन वनों की मृदा में मैंगनीज, जस्ता, मैंगनीशियम, ताँबा और लोहा अधिक मात्रा में रहने से संबन्धित है।
