#### Abstract

The experiment was carried out at the farm of Uttar Banga Krishi Viswavidyalaya, Pundibari, Cooch Behar, West Bengal from August to October of 2011-12 and 2012-13, respectively. To investigate the effect of phosphorus enriched vermicompost on yield of ground nut under irrigated conditions. The experiment was laid out in a RBD design with 14 treatments which replicated thrice. Highest pod yield was obtained from  $T_7$ , that receiving 150% phosphorus through rockphosphate enriched vermicompost grade-I) (2400.50 kg ha<sup>-1</sup>) whereas, the treatment receiving 100% recommended dose through sole application of chemical fertiliser ( $T_1$ ) (1479.00 kg ha<sup>-1</sup>) was lowest yield. Dry matter accumulation increased significantly with crop age. Pooled data revealed that  $T_7$  (4402.86 g m<sup>-2</sup>) performed better in all sampling days. The lowest Dry matter accumulation was observed in  $T_1$  (1096.66 g m<sup>-2</sup>). The treatment  $T_7$  recorded the highest value (4.02) of LAI at 75DAS and thereafter declined towards maturity. The highest value of 100-pod weight,100-kernel weights and harvest index were recorded in  $T_7$  respectively (93.22 gm) (63.56 gm) and. (44.04%).It was observed that haulm yield of  $T_4$  recorded highest value of haulm yield (3541.10 kg ha<sup>-1</sup>) and  $T_8$  recorded lowest value of haulm yield (3159.00 kg ha<sup>-1</sup>). Pooled data revealed that  $T_7$  has highest (86.43%) shelling out and  $T_1$  has the lowest value (57.84%). Among the Phosphorus use efficiency, Highest Partial factor of productivity and Agronomic efficiency were observed in  $T_5$  respectively (55.21 kg ha<sup>-1</sup>) and (29.99 kg ha<sup>-1</sup>). Apparent recovery was highest in  $T_7$  (306.46%) and maximum value of Physiological use efficiency was noticed in  $T_4$  (26.23 kg ha<sup>-1</sup>).

### 1. Introduction

The agro-climatic condition of terai zone is very much conducive for groundnut cultivation but soil constraints are there which prevent the farmers from taking some positive outlook about cultivation of this crop. Soil of North Bengal is mostly acidic which aggravates the problem of fixation of phosphorus and lower availability of micro-nutrients like zinc, boron etc. (Mandal, 1989), which leads to improper nodulation and poor yield of number of pulse and oilseed crops under the Fabaceae family. The efficiency of utilization of phosphatic fertilizer is very low (20-25 %) due to chemical fixation in soil. Besides, native soil phosphorus is mostly unavailable to crops because of its low solubility. Further there is build up of insoluble phosphates in soil where phosphatic

\*Author for correspondence

fertilizers have been applied over long periods. Hence, to reduce the phosphorus fixation in soil and to enhance the efficiency of the applied phosphatic fertilizer and to keep phosphorus more timely available to crops, organic matter plays a great role. Increasing plant biomass production per unit cropped area, increasing biomass return per unit to cropped area and decreasing soil organic matter loss have been identified as the major considerations to maintain the soil organic matter balance. Therefore, there is a need to develop viable technology to increases the Phosphorus use efficiency of inorganic P-fertilizer and yield through of enriched vermicompost.

## 2. Materials and Methods

The experiment was carried out at the farm of Uttar Banga Krishi Viswavidyalaya, Pundibari, Cooch Behar, West Bengal from August to October of 2011-12 and 2012-13, respectively. To investigate the effect of phosphorus enriched vermicompost on yield of ground nut under irrigated conditions.

The experiment was laid out in a RBD design with 14 treatments which replicated thrice viz., Grade-I = 2%rockphosphate and Grade-II = 3% rock phosphate; T<sub>1</sub> = 100% Phosphorus through SSP,  $T_2 = 75\%$  Phosphorus through SSP + 25% Phosphorus through enriched vermicompost (Grade I),  $T_3 = 50\%$  Phosphorus through SSP + 50% Phosphorus through enriched vermicompost (Grade I),  $T_4 = 25\%$  Phosphorus through SSP + 75% Phosphorus through enriched vermicompost (Grade I),  $T_5 = 100\%$ Phosphorus through enriched vermicompost (Grade I),  $T_6 = 125\%$  Phosphorus through enriched vermicompost (Grade I),  $T_7 = 150\%$  Phosphorus through enriched vermicompost (Grade I),  $T_s = 75\%$  Phosphorus through SSP + 25% Phosphorus through enriched vermicompost (Grade II),  $T_0 = 50\%$  Phosphorus through SSP + 50% Phosphorus through enriched vermicompost (Grade II),  $T_{10} = 25\%$  Phosphorus through SSP + 75% Phosphorus through enriched vermicompost (Grade II),  $T_{11} = 100\%$ Phosphorus through enriched vermicompost (Grade II),  $T_{12} = 125\%$  Phosphorus through enriched vermicompost (Grade II),  $T_{13} = 150\%$  Phosphorus through enriched vermicompost (Grade II),  $T_{14}$  = control plot.

The total content in the selected vermicompost were determined and the calculated quantity of each enriched vermicompost was taken separately and mixed well with single superphosphate to make exactly the double the quantity of phosphorus in each vermicompost. Single superphosphate mixed vermicompost was filled separately in polyethylene bag and required quantity of water was added to each bag to maintain moist condition (50% of maximum water retention capacity of the manure). These bags were kept for a period of one month by adding water as per the requirement to maintain uniform moisture level in the entire incubated time. After the incubation period of 30 days all these vermicompost were dried and applied to soil.

# 3. Results and Discussion

The ground nut yield in control plot was 1008.85 kg ha<sup>-1</sup> (Table 1) (Figure 1). Addition of P-enriched vermicompost increased the grain yield significantly to 2400.50 kg ha<sup>-1</sup>.

Highest pod yield was obtained from  $T_7$ , that receiving 150% phosphorus through rockphosphate enriched vermicompost grade-I (2400.50 kg ha<sup>-1</sup>) whereas, the treatment receiving 100% recommended dose through sole application of chemical fertiliser ( $T_1$ ) (1479.00 kg ha<sup>-1</sup>) was lowest yield.  $T_7$  (150% phosphorus through rockphosphate enriched vermicompost grade-I) was followed by  $T_6$  (125% phosphorus through rockphosphate enriched vermicompost grade-I) and  $T_5$  (100% phosphorus through rockphosphate enriched vermicompost grade-I) which were at par with each other Rasal et al.<sup>12</sup>, Raj et al.<sup>11</sup>, Ghosh et al.<sup>7</sup>, Saha and Hajra<sup>15</sup> and a number of authors experienced the higher pod yield of groundnut and other crops due to application of rockphosphate enriched compost over chemical fertiliser alone.

Dry matter accumulation (Table 2) (Figure 2) increased significantly with crop age. Sastry et al.<sup>16</sup> also recorded progressive increase in dry matter up to harvest of groundnut. From the destructive samplings at all the stages it was noticed that, treatment  $T_{z}$  (150% phosphorus through rockphosphate enriched vermicompost grade-I) recorded higher dry matter accumulation than  $T_{13}$ (150% rockphosphate enriched vermicompost grade-II). Treatment T<sub>1</sub> (100% phosphorus through SSP) i.e., sole application of chemical fertiliser at recommended dose recorded lowest values of dry matter accumulation in almost all sampling. The higher vegetative growth might be achieved by greater amount of available phosphorus in soil at important stages of growth, i.e., at 45 and 60 DAS (Table 4) which probably enabled the plant to grab higher amount of nutrient from the soil with greater root rhizosphere. Bhawalkar<sup>3</sup> experienced that vermicompost contains more number of N-fixing, P-solubilizing

and other beneficial microbes, antibiotics, vitamins, hormones, enzymes etc. which have better effects on growth and yield of plants. Gosh and Das Gupta<sup>8</sup>, Roopadevi et al.<sup>14</sup> experienced similar result.

There was an increasing trend of LAI (Table 3) (Figure 3) values up to 75 DAS and thereafter declined towards maturity, probably due to senescence of lower leaves. Pooled analysis of data from each sampling showed

that at 75 DAS the LAI was higher in T<sub>7</sub> (150% phosphorus through rockphosphate enriched vermicompost grade-I) (4.02) and T<sub>13</sub> (150% rockphosphate enriched vermicompost grade-II)(6.55) among organic treatment. Both the organic treatment T<sub>7</sub> (150% phosphorus through rockphosphate enriched vermicompost grade-I) (4.02) and T<sub>13</sub> (150% rockphosphate enriched vermicompost grade-II) had higher LAI than sole chemical treatment

 $T_1$  (100% phosphorus through SSP)(5.84). Better nutrient availability might have resulted in greater leaf area index. The trend was similar at later stages of observations too. Similar trends were also registered by Ghosh et al.<sup>7</sup>, Saha and Hajra<sup>15</sup> Figure 3).

Pooled data (Table 4) and (Figure 4) reveals that 100-pod weight in  $T_7$  (150% phosphorus through rock-phosphate enriched vermicompost grade-I) recorded highest value (93.22 gm) and  $T_{14}$  (control) exhibited the lowest value (61.08 gm) among the treatments. In general, irrespective of gradation of vermicompost with the increased in its application increased the 100-pod weight significantly. In general way, the data revealed that, wherever chemical fertiliser was substituted with grade-I, rockphosphate enriched vermicompost, increased the nutrient availability and uptake significantly and ultimately achieved higher value of 100-pod weight. Dayal and Agarwal<sup>4</sup>, Babalad<sup>2</sup>, Enyi<sup>6</sup>, Jaswal and Gupta<sup>9</sup>, Rahman and Rahman<sup>10</sup>, Ghosh et al.<sup>7</sup>, and Tiwari et al.<sup>18</sup> also reported similar result in different crops.

100-kernel weights (Table 4) and (Figure 4) varied significantly with different treatments (Table 4) and (Figure 4) Pooled data revealed that the  $T_7$  (150% phosphorus through rockphosphate enriched vermicompost grade-I) exhibited the highest value (63.56 gm) of 100-kernel weight, while  $T_1$  (100% phosphorus through SSP) recorded lowest value (53.82 gm) among the fertilized plots. The probable reason was higher available phosphorus and favourable soil condition in  $T_7$ . Shanwad<sup>17</sup>, Enyi<sup>6</sup>, Acuna and Sanchez<sup>1</sup> and Roopadevi et al.<sup>14</sup> also experienced the similar result in different crops.

It was observed (Table 5) and (Figure 5) that  $T_{4}$  (25%) phosphorus through SSP + 75% phosphorus through PC grade II) recorded highest value of haulm yield (3541.1), followed by  $T_{o}$  (50% phosphorus through SSP + 50% phosphorus through rockphosphate enriched vermicompost grade-II) and T<sub>1</sub> (100% phosphorus through SSP). Moreover, wherever more than 75% phosphorus through rockphosphate enriched vermicompost (grade -I) was applied (i.e. in  $T_7$ ,  $T_6$  and  $T_5$ ), also produced quite substantial amount of haulm growth to give the higher economic yield at the end. Ghosh et al.4 and Raundal et al.<sup>13</sup> also concluded same result with application of P enriched compost in legumes and cereals. T<sub>s</sub> (75% phosphorus through SSP + 25% phosphorus through VC grade-II) recorded lowest value of haulm yield (3159) due to lower vegetative growth. Roopadevi et al.14 also noticed same result.

The highest (86.43%) shelling out turn (%) (Table 4) (Figure 4) was found in  $T_7$  (150% phosphorus through

Table 4.Effect of rockphosphate enriched vermicompost on 100-pod weight (g), 100-kernelweight (g) and shelling outturn % at harvest of groundnut

**Figure 4.** Effect of rockphosphate enriched vermicompost on 100-pod weight (g), 100-kernel weight (g) and shelling out turn % at harvest of groundnut.

rockphosphate enriched vermicompost grade-I) and  $T_1$  (100% phosphorus through SSP) showed the lowest value (57.84%) and  $T_{13}$  (150% rockphosphate enriched vermicompost grade-II) (68.82%) was in 5<sup>th</sup> rank. This was due to higher kernel weight and lesser pod weight in  $T_7$  in comparison with other treatments. The general

information that surfaced from this data set that rockphosphate enriched vermicompost grade-I treated plots enhanced the nutrient availability and improved the percentage of shelling out turn significantly in comparison with chemical fertiliser treated plots. The treatments under grade-I vermicompost could able to

Figure 5. Effect of rockphosphate enriched vermicompost on pod yield, haulm yield and harvest index of groundnut at harvest.

supply all other essential elements apart from P in more balanced way, may be due to the better mineralization of organic matter under comfortable sphere of activity of earthworm.

The phosphorus through rockphosphate enriched vermicompost was applied in higher percentage, the

value of harvest index (Table 5) and (Figure 5) improved significantly. T<sub>7</sub> (150% phosphorus through rockphosphate enriched vermicompost grade-I) registered the highest value of harvest index in both the years (44.82% and 43.26%). The lowest value of harvest index was found in T<sub>2</sub> (75% phosphorus through SSP + 25% phosphorus

through grade I) in both years (33.73% and 33.89%). This was due to lower pod yield and higher biomass yield corresponding to the treatment. Ghosh et al.<sup>7</sup> also concluded similar result in P enriched compost.

Phosphorus use efficiency (Table 6) and (Figure 6) in case of Partial factor of productivity was highest for the treatment  $T_5$  (100% of rockphosphate enriched vermicompost grade-I) (55.21 kg ha<sup>-1</sup>) followed by  $T_4$  (25%)

rockphosphate through SSP + 75% phosphorus through phosphocompost grade–I) (54.63 kg ha<sup>-1</sup>). Lowest Partial factor of productivity was the T<sub>13</sub> (150% phosphorus through rockphosphate enriched vermicompost grade-I). Agronomic efficiency was higher in T<sub>5</sub> (100% of rockphosphate enriched vermicompost grade-I) (29.99 kg ha<sup>-1</sup>) followed by T<sub>4</sub> (25% rockphosphate through SSP + 75% phosphorus through phosphocompost grade–I)

Table 6.Effect of rockphosphate enriched vermicompost on Phosphorususe efficiency in ground nut

Treatments	Partial factor	Agronomic	Apparent	Physiological
	of productivity	efficiency (AE)	recovery (AR)	use efficiency
	(PFP) (kg/ha)	(kg/ha)	(%)	(PUE) (kg/ha)
T <sub>1</sub>	36.98	11.75	47.325	24.84
T <sub>2</sub>	42.34	17.12	99.825	17.15
T <sub>3</sub>	50.81	25.59	97.575	26.23
$T_4$	54.63	29.40	141.45	20.79
T <sub>5</sub>	55.21	29.99	219.8	13.64
T <sub>6</sub>	44.57	24.39	239.42	10.19
T <sub>7</sub>	40.01	23.19	306.4667	7.57
T <sub>8</sub>	39.83	14.60	104.1	14.03
Τ,	49.14	23.92	123.625	19.35
T <sub>10</sub>	50.05	24.83	179.925	13.80
T <sub>11</sub>	53.14	27.92	119.725	23.32
T <sub>12</sub>	42.68	22.50	244.22	9.21
T <sub>13</sub>	35.90	19.08	207.55	9.19

Figure 6. Effect of rockphosphate enriched vermicompost on Phosphorus use efficiency in ground nut.

(29.40 kg ha<sup>-1</sup>). However, Apparent recovery, was highest in  $T_{\tau}$  (150% phosphorus through rockphosphate enriched vermicompost grade-I) (306.46%) followed by  $T_{11}$  (100%) phosphorus through rockphosphate enriched vermicompost grade-II) (244.22%). In the same way maximum value of Physiological use efficiency was noticed under the treatment  $T_3$  (50% rockphosphate through SSP + 50% phosphorus through phosphocompost grade-I) (26.23 kg ha<sup>-1</sup>) and it was followed by  $T_4$  (25% rockphosphate through SSP+75%phosphorus through phosphocompost grade-I) (20.79 kg ha-1). However, rockphosphate enriched vermicompost treated plots recorded the lower values of Phosphorus use efficiency than the integrated treated plots might be due to corresponding higher values of absorbed phosphorus in applied plots. Thus it was very clear from this (Table 6) that organic sources of P increased the partial factor of productivity and Agronomic efficiency up to either 100% of its use or in integration with chemical. However in 125% and 150% organic treatments the availability of nutrient showed better and proved surplus for the standing crop which showed luxury consumption of nutrient by standing crop through it. Dwivedi<sup>5</sup> got more pronounced effect of P enriched compost on P use efficiency and relative agronomic effectiveness.

# 4. Conclusion

Pooled analysis of data of two years studies showed that highest pod yield was obtained from  $T_7$ , that receiving 150% phosphorus through rockphosphate enriched vermicompost grade-I) whereas, the treatment receiving 100% recommended dose through sole application of chemical fertiliser ( $T_1$ ) was lowest yield among the fertilized plots.  $T_7$  (150% phosphorus through rockphosphate enriched vermicompost grade-I) was followed by  $T_6$ (125% phosphorus through rockphosphate enriched vermicompost grade-I) and  $T_5$  (100% phosphorus through rockphosphate enriched vermicompost grade-I) which were at par with each other.

Dry matter accumulation for Treatment  $T_7$  ((150% phosphorus through rockphosphate enriched vermicompost grade-I) recorded higher dry matter accumulation than  $T_{13}$  (150% rockphosphate enriched vermicompost grade-II). Treatment  $T_1$  (100% phosphorus through SSP) recorded lowest values almost all sampling.

Increasing trend of LAI values up to 75 DAS and thereafter declined. Both the organic treatment  $\rm T_{_7}$  (150%

phosphorus through rockphosphate enriched vermicompost grade-I) and  $T_{13}$  (150% rockphosphate enriched vermicompost grade-II) had higher LAI than sole chemical treatment  $T_1$  (100% phosphorus through SSP).

In general way, the data revealed that, wherever chemical fertiliser was substituted with grade-I, rockphosphate enriched vermicompost, increased the nutrient availability and uptake significantly and ultimately achieved higher value of 100-pod weight.

100-kernel weights varied significantly with different treatments. Treatment  $T_7$  (150% phosphorus through rockphosphate enriched vermicompost grade-I) exhibited the highest value of 100-kernel weight, while  $T_1$  (100% phosphorus through SSP) recorded the lowest value among the fertilized plots.

Treatment  $T_4$  (25% phosphorus through SSP+75% phosphorus through PC grade II) recorded highest value of haulm yield (3541.1), followed by  $T_9$  (50% phosphorus through SSP + 50% phosphorus through rockphosphate enriched vermicompost grade-II) and  $T_1$  (100% phosphorus through SSP).

Rockphosphate enriched vermicompost grade-I treated plots enhanced the nutrient availability and improved the percentage of shelling out turn significantly in comparison with chemical fertiliser treated plots may be due to the better mineralization of organic matter under comfortable sphere of activity of earthworm.

Higher percentage the value of harvest index observe in T<sub>7</sub> (150% phosphorus through rockphosphate enriched vermicompost grade-I) registered the highest value of harvest index in both the years. The lowest value of harvest index was found in T<sub>2</sub> (75% phosphorus through SSP + 25% phosphorus through grade-I) in both years. This was due to lower pod yield and higher biomass yield corresponding to the treatment.

It was very clear from this result that organic sources of P increased the partial factor of productivity and Agronomic efficiency up to either 100% of its use or in integration with chemical. However in 125% and 150% organic treatments the availability of nutrient showed better and proved surplus for the standing crop which showed luxury consumption of nutrient by standing crop through it.
